The Moral Psychology Lab uses multiple methods to study moral development. We use cognitive experimental methods like reading stories, watching shows, playing video games and asking about recall or inferences. We use survey methods to study personality, political and developmental differences informed by moral philosophy, using correlational and modeling techniques to examine relations among variables. We use observational methods to study children's moral development. Our recent topics include early caregiving and moral development, academic integrity, moral judgment, moral identity, attachment, aggression, political attitudes, ecological reverence, multicultural experience. Undergraduates help conceptualize and design studies, collect, enter and score data; present findings at conferences, develop interventions with local communities, co-author papers, and assist in summer research.
